IEEE Working Group P3109 Interim Report
on 8-bit Binary Floating-point Formats

Questions and comments via GitHub issues at
https://github.com/P3109/Public

Initial release: 18 September 2023

Version 0.6.3: 20 February 2024 (compiled 2024-02-20)

DRAFT DOCUMENT

Contents

1   Introduction

This document represents ongoing discussions and current matters of consensus from IEEE Working Group P3109, "Standard for Arithmetic Formats for Machine Learning". The Project Authorization Request (PAR) for P3109 defines the scope, need, and stakeholders as follows:

> **Scope of proposed standard**: This standard defines a binary arithmetic and data format for machine learning-optimized domains. It also specifies the default handling of exceptions that occur in this arithmetic. This standard provides a consistent and flexible arithmetic framework optimized for Machine Learning Systems (MLS) in hardware and/or software implementations to minimize the work required to make MLS interoperable with each other, as well as other dependent systems. This standard is aligned with IEEE Std 754-2019for Floating-Point Arithmetic.

> **Need for this Work**: Machine Learning Systems have different arithmetic requirements from most other domains. Precisions tend to be lower, and accuracy is measured in dimensions other than just numerical (e.g. inference accuracy). Furthermore, machine learning systems are often integrated into mission-critical and safety-critical systems. With no standards specifically addressing these needs, Machine Learning Systems are built with inconsistent expectations and assumptions that hinder the compatibility and reuse of machine learning hardware, software, and training data.

> **Stakeholders for the Standard**: System developers, vendors, and users of machine learning applications across many industries and interests including but not limited to computation, storage, medical, telecommunications, e-commerce, fleet management, automotive, robotics, and security.

The scope of this interim release is interchange formats, classification operators, and comparisons. The working group continues to deliberate on the specification of additional operations.

1.1   Typographical conventions and notation

Bold text describes the decisions and specifications of this document.

Text that is not bold is background material, typically providing rationale and arguments that represent discussions of the working group leading to a decision and specification.

This document specifies 8-bit floating-point interchange formats (binary formats) and associated operations. Binary formats are parameterized by their width, the number of bits spanned in memory (here, 8); and their precision (P), the number of bits spanned by the true significand (this is one more than the bits of the significand that are stored explicitly).

The formats defined herein shall be referred to as "binary8" formats, and further qualified by precision yielding names "binary8pP**" for values** $1 \leq P \leq 7$**.**

For example, "binary8p3" is a format with 3 bits of precision; one bit is an implicit leading bit and two bits are explicit.

2 Values

This section describes the set of values that a binary8 format shall represent. The universe of values in existing floating point usage encompasses some finite real numerical values, the non-finite numerical values positive and negative infinity ($-$Inf, $+$Inf), the non-numeric not-a-number values (NaN, NaN_1, . . .), and negative zero (-0). The value set for each binary8 format specifies the set of values that are available in that format.

Each binary format shall be associated with a unique encoding. An 8-bit binary encoding is a mapping from 8-bit strings to values. Some of these mappings are included in Appendix C.

Values are considered either "special" or "ordinary". Encodings of the special values, shared by all binary8 formats, are shown in Table 1 as Zero, $+$Inf, $-$Inf, and NaN. The binary8 formats have only a single NaN, and relocate it to the -0 position, providing an increased range. The ordinary values consist of the normal and subnormal values.

Table 1: Special value encodings

Special Value	Symbol	Hexadecimal Encoding	Bit Sequence
Zero	0	0x00	0000 0000
Positive Infinity	$+$Inf	0x7F	0111 1111
Negative Infinity	$-$Inf	0xFF	1111 1111
Not a Number	NaN	0x80	1000 0000

These mappings are shared by all binary8 formats.

Table 2: Parameters for binary formats

Symbol	Parameter Description	Derived Value	binary8pP, K = 8, P =							IEEE754-2019, K =		
			7	6	5	4	3	2	1	16	32	64
K	**storage (bits)**	**K**	**8**	**8**	**8**	**8**	**8**	**8**	**8**	**16**	**32**	**64**
P	**precision (bits)**	**P**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**11**	**24**	**53**
S	sign (bits)	1	1	1	1	1	1	1	1	1	1	1
W	exponent (bits)	$K - P$	1	2	3	4	5	6	7	5	8	11
T	trailing significand (bits)	$P - 1$	6	5	4	3	2	1	0	10	23	52
SE	all-special exponent	SE	0	0	0	0	0	0	1	1	1	1
emax	maximum exponent	$2^{W-1} - 1$	0	1	3	7	15	31	63	15	127	1023
emin	minimum exponent	$SE - emax$	0	-1	-3	-7	-15	-31	-62	-14	-126	-1022
bias	exponent bias	$1 - emin$	1	2	4	8	16	32	63	15	127	1023

Format-defining parameters in bold, derived parameters in normal font.
Adapted from Table 3.5 of IEEE Std 754-2019, and extended to include
the binary8pP formats. Concepts are explained in detail in this section.

The finite floating-point numbers representable with a binary format are determined by two *format-defining* parameters:

- Storage width K, the total size of the format in bits

- Precision P, the number of digits in the significand including the implicit leading bit.

4

With binary8P1 and IEEE Std 754, there is one exponent symbol (all ones) that contains only special NaN and/or Inf values – this is indicated by the *all-special exponent* symbol, SE. When SE = 1, the bias parameter is odd and emin is even.

All other parameters, such as the exponent of the largest finite value emax, are derived from the format-defining parameters. Unlike IEEE Std 754, the bias term in the binary8 formats is typically even. This allows a more symmetrical range, where emin = −emax, and arises in most binary8 formats (except P = 1).[1] While it is believed this symmetry will be useful, we need to find additional rationale to support this decision.

For P ≥ 3, we note the binary8pP value sets are subsets of the IEEE Std 754 binary16 value set.

IEEE Std 754-2019 includes the radix B and the minimum exponent emin in a list of format-defining parameters, this document excludes both of them for these two reasons:

- This document covers binary (radix 2) formats only, so B is not a format parameter.

- The quantity emin is determined by P and emax; it cannot be varied independently, so it cannot be a format-defining parameter.

The P3109 committee has not yet fully reconciled the following notes from IEEE Std 754-2019:

- For binary formats, the precision p should be at least 3, as some numerical properties do not hold for lower precisions.

- Similarly, emax should be at least 2 to support the operations listed in 9.2.

The operations referred to in 9.2 are sin/cos/exp/log/etc.

It is unclear whether adopting P = 8 into the binary8 family provides any value. Strictly following Table 2, emax = −$\frac{1}{2}$ which means all ordinary values are irrational. Rounding this computation upward yields emax(8) = 0 and bias(8) = 1, where all representations within the format are subnormal, with the consequence that the value sets and encodings for binary8p7 and binary8p8 are identical except for a scaling factor of 1/2. As these different binary8p8 encodings are largely redundant with binary8p7, this interpretation does not appear to be useful. Finally, we could define P = 8 as a special case, e.g. a signed-magnitude Q7.0 integer representation with a range of 0 to 126 plus the special encodings for NaN, +Inf, and −Inf. This last interpretation, where binary8p8 is an 8-bit integer representation, might be useful in some training situations where the special values or saturating features are useful. However, at the moment, P = 8 remains outside of the scope of P3109.

2.1 **Notes on** emax

The choice of emax for a given format then determines the exponent bias for that format. The bias is chosen so that the exponent of the largest finite value is emax. For IEEE Std 754 formats, the largest finite value corresponds to an exponent field which has all but the zeroth bit set (e.g. 11110 for binary16), because all of the values with all-bits-one exponents are occupied by non-finite values (Not-a-Numbers or Infinities). Thus, the biased exponent of the largest finite value is $2^W - 2$, from which bias should be defined so that

$$(2^W - 2) - \text{bias} = \text{emax}$$

Rearranging, we obtain the following for IEEE Std 754 formats

$$\text{bias} = (2^W - 2) - (2^{W-1} - 1) = 2 \cdot (2^{W-1} - 1) - (2^{W-1} - 1) = 2^{W-1} - 1 = \text{emax}$$

---

[1]The binary8p1 encoding is different because there are no bits in the significand allowing it to distinguish Inf from finite values.

For the binary8 formats in this document where $P > 1$, only one of the values that has exponents with all-bits-one is non-finite ($\pm$Inf), so the biased exponent of the largest finite value is $2^W - 1$. Hence the bias calculation becomes

$$\text{bias} = (2^W - 1) - (2^{W-1} - 1) = 2^{W-1} - 1 + 1 = \text{emax} + 1$$

For $P = 1$, there are zero trailing significand bits, so all values where the exponent bits are ones are special, and again bias = emax.

2.2 Subnormals

Binary8 value sets shall include subnormals.

IEEE Std 754 value sets include subnormals. A value with trailing significand field T and exponent field E is interpreted as $1.T \times 2^{E-\text{bias}}$ except when all bits of the exponent bitfield are 0, in which case the value is $0.T \times 2^{1-\text{bias}}$.

Subnormal numbers extend the dynamic range of floating-point values and induce equal quantization steps close to zero. They can be useful when training models, where it is common to represent near-zero values for gradients. Subnormals can also be useful to represent random values pulled from certain distributions. For example, model weights are initialized to small random values at training. Subnormals are uniformly spaced around zero, and values near zero are more probable in Gaussian-like distributions values. Finally, formats with narrow exponent widths necessarily have a limited range; subnormals extend this range by a power of 2 for every bit in the trailing significand.[2]

2.3 Not a number (NaN)

Binary8 value sets shall include exactly one NaN, encoded as 0x80, which shall not signal.

Many other floating-point formats define several NaN values which are returned from operations with results outside the set of values, e.g., $\text{DIV}(0,0)$, or $\text{ADD}(+\text{Inf}, -\text{Inf})$. Multiple NaN encodings are used in other formats to allow different exceptional conditions to be distinguished.

In the context of machine learning systems, uses of NaN include:

- Debugging of code running on accelerator hardware. In A.I. accelerators, exceptions may be difficult or expensive to convey back to user code, so it is common practice to allow NaN values to propagate through calculations to indicate that an error has occurred.

- Use as a sentinal value. In some datasets, for example, where individual element values may be missing or out of range, a sentinal may be used to record the position of these values. In many cases, this will require less memory than storing such information out-of-band, such as in a coordinate-list (COO) format array. In some cases, $\pm$Inf can be used as a missing value, but given the restricted range of binary8 formats, it is likely that infinity shall be used as a separate indicator of rounding from values outside of the finite range.

- The use of multiple NaN payloads is known in statistical code (e.g. the R system has NaN and N/A), but it is not widely used. In the context of binary8, supporting multiple NaNs would reduce the already limited encoding space (e.g., occupying all code points where the exponent field is all ones, thereby reducing dynamic range) and would likely add additional hardware complexity.

---

[2]Conversely, subnormals provide a limited range increase to formats with narrow significands.

2.4 Zero

Binary8 formats shall have exactly one zero, encoded as 0x00. This zero value is nonnegative.

The inclusion of negative zero (–0) would incur the cost of an additional code point. Given the decision to encode only a single NaN, placing that NaN at the negative zero code point enables the strictly positive and strictly negative number ranges to be symmetric.

A key rationale for including –0 in IEEE Std 754was the consistent implementation of branch cuts in the atan2 function [4, 5]. Although the atan function is common in deep learning, it is generally used as an activation function, rather than a trigonometric operation, and the atan2 function is rare, if not unknown, in deep learning applications. Hence, it is not expected that this standard shall define either atan or atan2.

A secondary reason for providing –0 is the hardware simplification offered by its presence in the implementation of sign/magnitude arithmetic. However, the existence of in-market implementations is evidence that the small hardware simplification has not been sufficient to balance the loss of one code point.

It might be considered that the use of integer comparisons in sorting would argue against placing NaN at the negative zero code point. For example, the JAX machine learning framework is known to sort using integer comparison [3]. However, such sorting still requires $O(n)$ preprocessing and postprocessing steps to enable the use of twos-complement integer comparison, and already has special treatment of NaN and -0, so eliminating –0 and placing NaN in the –0 position imposes negligible additional burden.[3]

2.5 Infinities

Binary8 formats shall include positive and negative infinities, encoded as 0x7f and 0xff, respectively.

This decision causes a reduction in dynamic range (252 values rather than 254), while offering improved numerical robustness in important machine learning use cases.

Examples of such usage are:

- Mask values, for example, in Transformer models in machine learning [1].

- Representation of overflow, for example, to adjust dynamic loss scaling factors [7].

As illustrated in Appendix A, both uses are facilitated by the presence of infinity.

---

[3]Sorting using comparison operations is undefined in the presence of NaNs. However, existing practice is to sort NaNs using totalOrder.

2.6 Extremal values

Table 3: Extremal values

Format	minSubnormal	maxSubnormal	minNormal	maxNormal	maxFinite
binary8p1	N/A	N/A	1×2^{-62}	1×2^{63}	1×2^{63}
binary8p2	1×2^{-32}	1×2^{-32}	1×2^{-31}	1×2^{31}	1×2^{31}
binary8p3	1×2^{-17}	$3/2 \times 2^{-16}$	1×2^{-15}	$3/2 \times 2^{15}$	$3/2 \times 2^{15}$
binary8p4	1×2^{-10}	$7/4 \times 2^{-8}$	1×2^{-7}	$7/4 \times 2^{7}$	$7/4 \times 2^{7}$
binary8p5	1×2^{-7}	$15/8 \times 2^{-4}$	1×2^{-3}	$15/8 \times 2^{3}$	$15/8 \times 2^{3}$
binary8p6	1×2^{-6}	$31/16 \times 2^{-2}$	1×2^{-1}	$31/16 \times 2^{1}$	$31/16 \times 2^{1}$
binary8p7	1×2^{-6}	$63/32 \times 2^{-1}$	1×2^{0}	$63/32 \times 2^{0}$	$63/32 \times 2^{0}$

It is practical to list extremal finite values defined by the binary8 formats. Following IEEE Std 754-2019 naming patterns, we adopt: $\mathsf{maxNormal}(\tau), \mathsf{minNormal}(\tau), \mathsf{minSubnormal}(\tau)$ where τ is a binary8 format. For example: $\mathsf{maxNormal}(\mathsf{binary8p4}) = 7/4 \times 2^{7}$ and $\mathsf{minNormal}(\mathsf{binary8p5}) = 1 \times 2^{-3}$.

Table 3 shows the extremal values for $1 \leq p \leq 7$. For reference, section C provides complete tables of values.

2.7 Equivalents

The binary8p7 format is equivalent to a signed-magnitude fixed-point integer in Q1.6 format, except there are code points reserved for NaN, $+\mathsf{Inf}$, and $-\mathsf{Inf}$.

3 Classification operators

Conforming implementations shall provide the classification predicates defined by Table 4 and the classifier operator defined by Table 5. The classification predicates and the classifier function shall not signal exceptions.

The classification operators comprise: 1) a set of predicate functions with a boolean return value, taking a single binary8 value as input; 2) a classifier operator $\text{class}(x)$ that returns a single value of enumeration type, describing the input value's properties.

3.1 Classification predicates

Classification predicates shall behave as defined by Table 4.

Table 4: Predicate logic

Predicate	Definition
isZero(x)	iff x is Zero
isNaN(x)	iff x is NaN
isInfinite(x)	iff x is infinite
isFinite(x)	iff x is zero, subnormal or normal
isNormal(x)	iff x is normal, hence finite
isSubnormal(x)	iff x is subnormal
isSignMinus(x)	iff x has a negative sign [a]
isCanonical(x)	True [b]
isSignaling(x)	False [c]

[a] isSignMinus(NaN) is True: NaN is 0x80 (0b1000_0000).
[b] There are no non-canonical binary8 interchange formats.
[c] All binary8 formats have one NaN; it does not signal.

3.2 Classifier operator

The Classifier operator $\text{class}(x)$ tells which of the eight classes x falls into as defined by Table 5.

Table 5: Classifier operator

Enumeration	Condition
NaN	isNaN(x)
negativeInfinity	isInfinite(x) and isSignMinus(x)
negativeNormal	isNormal(x) and isSignMinus(x)
negativeSubnormal	isSubnormal(x) and isSignMinus(x)
Zero	isZero(x)
positiveSubnormal	isSubnormal(x) and not(isSignMinus(x))
positiveNormal	isNormal(x) and not(isSignMinus(x))
positiveInfinity	isInfinite(x) and not(isSignMinus(x))

4 Comparison Predicates

Conforming implementations shall provide the comparison predicates defined by Table 6 and the $\mathrm{totalOrder}(x, y)$ **predicate.**

4.1 Details of comparison predicates

Comparison operations are two-argument predicates, and their negations, that return True or False. Comparisons shall not raise exceptions. Comparisons may be ordered or unordered. A comparison is considered unordered iff either argument is NaN. All other comparisons are ordered.

For $\{=, >, \geq, <, \leq, \lesseqgtr\}$, if any argument is NaN, the result is False.

For $\{\neq, \not>, \not\geq, \not<, \not\leq, \not\lesseqgtr\}$, if any argument is NaN, the result is True.

Otherwise, the result of a comparison shall match the mathematical result.

Table 6: Comparison predicates and negations

Math symbol	Predicate *true relations*	Math symbol	Negation of predicate *true relations*
$=$	compareEqual *equal*	$\neq$, NOT $=$	compareNotEqual *less than, greater than, unordered*
$>$	compareGreater *greater than*	$\not>$, NOT $>$	compareNotGreater *less than, equal, unordered*
$\geq$	compareGreaterEqual *greater than, equal*	$\not\geq$, NOT $\geq$	compareLessUnordered *less than, unordered*
$<$	compareLess *less than*	$\not<$, NOT $<$	compareNotLess *greater than, equal, unordered*
$\leq$	compareLessEqual *less than, equal*	$\not\leq$, NOT $\leq$	compareGreaterUnordered *greater than, unordered*
$\lesseqgtr$	compareOrdered *less than, equal, greater than*	$\not\lesseqgtr$, NOT $\lesseqgtr$	compareUnordered *unordered*

4.2 Details of $\mathrm{totalOrder}$ predicate

The $\mathrm{totalOrder}(x, y)$ **predicate provides a total ordering over each binary8 format's value set and shall return { True, False } as defined by the logic below. It shall not raise any exceptions.**

```
boolean totalOrder(x, y)
    if isNaN(x): return True
    if isNaN(y): return False
    return compareLessEqual(x, y)
end
```

11

The above definition is consistent with the IEEE Std 754-2019 definition of $totalOrder$. In particular, among binary8 formats, there is a single NaN and it always compares as the most-negative value.

Question: should we define $totalOrder(x, y)$ between different binary8 formats, e.g. between binary8p5 and binary8p4? Should we ensure that comparison predicates are also defined between different binary8 formats?

Question: do any of our binary8 formats have redundant representations for the same number, particularly when different formats are compared? if so, totalOrder() in IEEE Std 754-2019 defines additional sorting by exponent magnitude that we'll have to add here:

```
if( x==y ) {
  if isNegative(x) return Exponent(x) >= Exponent(y)
  else             return Exponent(x) <= Exponent(y)
}
```

A Rationales

This section is being rewritten

A.1 Exponent bias

- we chose to follow 754 in defining emax - we could alternatively have defined bias consistently

this would mean no round tripping to b16

but means conversion to b16 requires and add or subtraction of one

conversion *from* b16 is expensive anyway...

A.2 Infinity

A.2.1 Mask Values

A common use for ∞ is to create masks, for example, in Transformer models in machine learning [1].

use $\beta = 1/t$. https://openreview.net/pdf?id=LBA2Jj5Gqn

These values, assembled in mask matrix M with values $M_{ij} \in \{0, -\infty\}$ are typically added to computed values A, in a computation such as:
$$\log(\mathrm{sum}(\exp(t * (A + M))))$$

where t is a "temperature" or "base" parameter [2]. This calculation depends on the property $\exp(t * (A_{ij} - \infty)) = 0$.

If a floating point encoding does not provide infinity, then instead M_{ij} will be replaced by a large float (e.g. 224 is the largest finite binary8p4 value). This is not in itself a difficulty: if all the A values are bounded (e.g. the results of a softmax operation are bounded above by 1.0), then $\exp(1.0 - 224.0)$ is an extremely small number, which will certainly round to zero. Therefore, an explicit representation of infinity is *not* needed in order for this computation to yield its desired value.

However, careful implementations do not execute the calculation as written, and instead fuse the $\log(\mathrm{sum}(\exp(v)))$ operation into a single operation $\mathrm{logsumexp}(v)$, whose implementation makes use of the identity transformation

$$\mathrm{logsumexp}(v) \to \mathrm{logsumexp}(v - \max(v)) + \max(v)$$

Without the "sticky" properties of Inf, this would produce incorrect answers.

For example, in a format where maxFinite=240 without Inf, and maxFinite=224 with Inf:

$$\mathrm{logsumexp}(t * [-224, -\infty]) \to \mathrm{logsumexp}(t * [0, -\infty])$$

while

$$\mathrm{logsumexp}(t * [-224, -240]) \to \mathrm{logsumexp}(t * [0, -16])$$

If $t = 1$ and all calculations are done in 8-bit floating point, then the answer will be the same, because $\exp(-16) \approx 1.1 \times 10^{-7}$, which will round to zero in all precisions $\mathsf{P} > 2$; but if t is small, or calculations are done in mixed precision, as is common with 8-bit floating point, the loss of "stickiness" will silently yield unexpected answers. It is not expected that the full calculation shall be done in 8-bit floating point, but the subtraction of the maximum value (and computation of the maximum) might reasonably be in 8-bit floating point.

A.2.2 Overflow to Infinity

A second use of infinity is to indicate overflow on conversion to the binary8 type. Existing implementations offer several behaviors on overflow: overflow to infinity, saturation to MaxFloat, and overflow to NaN. The existence of a code point for infinity allows any of these options to be implemented in a given instantiation, while removing the code point removes the possibility of implementing the first.

A.3 Eight Bit Formats

Eight bit floating-point representations have received much attention for their usefulness and efficacy in machine learning, especially deep learning. Various 8-bit floating-point formats have been proposed, investigated in research papers, and some have been modeled in software. Four precisions [3, 4, 5, and 6 bit precisions] have become generally accepted as providing greater operational benefits than the others. Overall [there are exceptions], current efforts focus more on precisions of 3 and 4 bits (exponent fields of 5 and 4 bits, respectively). The specifics of third-party proposals for 8-bit floating-point representations vary and can differ from one precision to another. Regardless, the precisions emphasized in current research and other third-party work do share the same focus.

A.3.1 binary8p3

This format has 3 subnormal and 123 normal magnitudes. The subnormal magnitudes cover $[1.0 * 2^{-17}, 3.0 * 2^{-17}]$. The normal magnitudes cover $[1.0 * 2^{-15}, 4195.0]$, There are 31 normal binades with 4 magnitudes per complete binade [binade 2^{15} has 3 magnitudes, the 4th is used for Inf].

A.3.2 binary8p4

This format has 7 subnormal and 119 normal magnitudes. The subnormal magnitudes cover $[1.0 * 2^{-10}, 7.0 * 2^{-10}]$. The normal magnitudes cover $[1.0 * 2^{-7}, 224.0]$. There are 15 normal binades with 8 magnitudes per complete binade [binade 2^7 has 7 magnitudes, the 8th is used for Inf],

A.3.3 binary8p5

This format has 15 subnormal and 111 normal magnitudes. The subnormal magnitudes cover $[1.0 * 2^{-7}, 15.0 * 2^{-7}]$. The normal magnitudes cover $[0.125, 15.0]$. There are 7 normal binades with 16 magnitudes per complete binade [binade 2^3 has 15 magnitudes, the 16th is used for Inf],

A.3.4 binary8p6

This format has 31 subnormal and 95 normal magnitudes. The subnormal magnitudes cover $[1.0 * 2^{-6}, 31.0 * 2^{-6}]$. The normal magnitudes cover $[0.5, 3.875]$. There are 3 normal binades with 32 magnitudes per complete binade [binade 2^1 has 31 magnitudes, the 32nd is used for Inf],

B External Formats

This table summarizes the points of agreement and of difference between the formats proposed in this document and a number of existing formats, some of which have hardware implementations.

OCP: Open Compute Platform [6], describing hardware implementations including nVidia, Intel, and ARM.

AGQ: AMD, Graphcore, Qualcomm[8], implemented in Graphcore's C600 product, and AMD's gfx940.

TSL: Tesla Dojo Technology [9], A Guide to Tesla's Configurable Floating Point Formats & Arithmetic

Format	P3109			OCP		AGQ		TSL	
Subformat	P3	P4	P5	E5	E4	E5	E4	E4	E5
Special values shared by all subformats	Y			N		Y		N	
Exactly one NaN	Y			N		Y		Y	
Positive and negative infinity	Y			Y	N	N		N	
Include negative zero	N			Y		N		N	
Max exponent emax	15	7	3	15	8	15	7	N/A	N/A

C Value Tables

Value tables mapping 8-bit strings to value sets are provided in this section.

A typical entry is of the form:

```
HEX  = BINARY     = BINARY_FLOAT  = DECIMAL
0x0b = 0_0001_011 = +0b1.011×2^-7 = 0.0107421875
```

Where the fields are interpreted as follows:

HEX	Hexadecimal encoding of the code point
BINARY	Binary expansion of the code point, underscores separate sign_exponent_significand
BINARY_FLOAT	The precise float value as a binary fraction followed by 2^e with decimal exponent e
DECIMAL	A decimal expansion of the value. If the expansion is not an exact representation of the precise float value, the equals sign is replaced by "approximately equals" $\approx$.

In addition, entries for subnormal and special values are rendered in color as follows:

```
0x05 = 0_0000_101 = +0b0.101×2^-7 = 0.0048828125     Subnormal value
0x80 = 1_0000_000 = NaN                              Special value (NaN, +Inf, -Inf)
```

15

C.1 Value Table: P1, $P = 1, \mathrm{emax} = 63$

0x00 = 0_0000000_ = 0.0	0x40 = 0_1000000_ = +0b1.0×2^1 = 2.0	0x80 = 1_0000000_ = NaN	0xc0 = 1_1000000_ = −0b1.0×2^1 = -2.0
